5.1.3.14 `dynallocate()` [1/2]

```
template<class B , typename... Args>
B & GiNaC::dynallocate (
    Args &&... args) [inline]
```

Constructs a new (class basic or derived) B object on the heap.

This function picks the object's ctor based on the given argument types.

This helps the constructor of `ex` from basic (or a derived class B) because then the constructor doesn't have to duplicate the object onto the heap. See [ex::construct_from_basic\(const basic &\)](#) for more information.

5.1.3.136 is_exactly_a() [2/2]

```

template<class T >
bool GiNaC::is_exactly_a (
    const ex & obj) [inline]

```

Check if `ex` is a handle to a `T`, not including base classes.

5.1.3.137 ex_to()

```

template<class T >
const T & GiNaC::ex_to (
    const ex & e) [inline]

```

Return a reference to the basic-derived class `T` object embedded in an expression.

This is fast but unsafe: the result is undefined if the expression does not contain a `T` object at its top level. Hence, you should generally check the type of `e` first. Also, you shouldn't cache the returned reference because `GiNaC`'s garbage collector may destroy the referenced object any time it's used in another expression.

Parameters

<code>e</code>	expression
----------------	------------

Returns

reference to object of class T

5.1.3.148 factor()

```
ex GiNaC::factor (
    const ex & poly,
    unsigned options)
```

Interface function to the outside world.

Factorizes univariate and multivariate polynomials.

It uses `factor1()` on each of the explicitly present factors of `poly`.

The default option is `factor_options::polynomial`, which means that `factor()` will only factorize an expression if it is a proper polynomial (i.e. the flag `info_flags::polynomial` is set). Given the option `factor_options::all`, `factor()` will factorize all subexpressions, e.g. polynomials containing functions or polynomials inside function arguments.

Parameters

in	<i>options</i>	see GiNaC::factor_options

Returns

5.1.3.157 make_hash_seed()

```
static unsigned GiNaC::make_hash_seed (
    const std::type_info & tinfo) [inline], [static]
```

We need a hash function which gives different values for objects of different types.

Hence we need some unique integer for each type. Fortunately, standard C++ RTTI class 'type_info' stores a pointer to mangled type name. Normally this pointer is the same for all objects of the same type (although it changes from run to run), so it can be used for computing hashes. However, on some platforms (such as woe32) the pointer returned by `type_info::name()` might be different even for objects of the same type! Hence we need to resort to comparing string representation of the (mangled) type names. This is quite expensive, so we compare `crc32` hashes of those strings. We might get more hash collisions (and slower evaluation as a result), but being a bit slower is much better than being wrong.

```
const numeric GiNaC::fsolve (

    const symbol & x,
    const numeric & x1,
    const numeric & x2)
```

Find a real root of real-valued function $f(x)$ numerically within a given interval.

The function must change sign across interval. Uses Newton- Raphson method combined with bisection in order to guarantee convergence.

Parameters

f	Function $f(x)$
x	Symbol $f(x)$
$x1$	lower interval limit
$x2$	upper interval limit

Exceptions

<code>runtime_error</code>	(if interval is invalid).

```

Numeric integration routine based upon the "Adaptive Quadrature" one in "Numerical Analysis" by Burden and Faires.

Parameters are integration variable, left boundary, right boundary, function to be integrated and the relative integration error. The function should evalf into a number after substituting the integration variable by a number. Another thing to note is that this implementation is no good at integrating functions with discontinuities.

5.1.3.486 kronecker_symbol()

```
numeric GiNaC::kronecker_symbol (

Returns the Kronecker symbol a : integer n : integer.

This routine defines $\text{kronecker_symbol}(1,0) = 1$ $\text{kronecker_symbol}(-1,0) = 1$ $\text{kronecker_symbol}(a,0) = 0$, $a \neq 1, -1$

In particular $\text{kronecker_symbol}(-1,0) = 1$ (in agreement with Sage)

    const std::vector< bool > & substed,
    std::vector< bool > & matched)
```

Checks whether e matches to the pattern pat and the (possibly to be updated) list of replacements repls.

This matching is in the sense of algebraic substitutions. Matching starts with pat.op(factor) of the pattern because the factors before this one have already been matched. The (possibly updated) number of matches is in nummatches. substed[i] is true for factors that already have been replaced by previous substitutions and matched[i] is true for factors that have been matched by the current match.

Parameters

<i>e</i>	expression to search
<i>x</i>	first symbol found (returned)

static void GiNaC::get_symbol_stats (

    const ex & b,
    sym\_desc\_vec & v) [static]
```

Collect statistical information about symbols in polynomials.

This function fills in a vector of "sym_desc" structs which contain information about the highest and lowest degrees of all symbols that appear in two polynomials. The vector is then sorted by minimum degree (lowest to highest). The information gathered by this function is used by the GCD routines to identify trivial factors and to determine which variable to choose as the main variable for GCD computation.

Parameters

<i>a</i>	first multivariate polynomial
<i>b</i>	second multivariate polynomial
<i>v</i>	vector of sym_desc structs (filled in)

static bool GiNaC::divide_in_z (

    ex & q,
    sym_desc_vec::const_iterator var) [static]
```

Exact polynomial division of $a(X)$ by $b(X)$ in $\mathbb{Z}[X]$.

This functions works like [divide\(\)](#) but the input and output polynomials are in $\mathbb{Z}[X]$ instead of $\mathbb{Q}[X]$ (i.e. they have integer coefficients). Unlike [divide\(\)](#), it doesn't check whether the input polynomials really are integer polynomials, so be careful of what you pass in. Also, you have to run [get_symbol_stats\(\)](#) over the input polynomials before calling this function and pass an iterator to the first element of the [sym_desc](#) vector. This function is used internally by the [heur_gcd\(\)](#).

Parameters

<i>a</i>	first multivariate polynomial (dividend)
<i>b</i>	second multivariate polynomial (divisor)
<i>q</i>	quotient (returned)
<i>var</i>	iterator to first element of vector of sym_desc structs

Returns

"true" when exact division succeeds (the quotient is returned in q), "false" otherwise.

Returns

a square-free factorization of a .

Note

A polynomial $p(X) \in C[X]$ is said *square-free* if, whenever any two polynomials $q(X)$ and $r(X)$ are such that

$$p(X) = q(X)^2 r(X),$$

we have $q(X) \in C$. This means that $p(X)$ has no repeated factors, apart eventually from constants. Given a polynomial $p(X) \in C[X]$, we say that the decomposition

$$p(X) = b \cdot p_1(X)^{a_1} \cdot p_2(X)^{a_2} \cdots p_r(X)^{a_r}$$

is a *square-free factorization* of $p(X)$ if the following conditions hold:

1. $b \in C$ and $b \neq 0$;

2. a_i is a positive integer for $i = 1, \dots, r$;
3. the degree of the polynomial p_i is strictly positive for $i = 1, \dots, r$;
4. the polynomial $\prod_{i=1}^r p_i(X)$ is square-free.

Square-free factorizations need not be unique. For example, if a_i is even, we could change the polynomial $p_i(X)$ into $-p_i(X)$. Observe also that the factors $p_i(X)$ need not be irreducible polynomials.

5.1.3.586 replace_with_symbol() [1/2]

```
static ex GiNaC::replace_with_symbol (
    const ex & e,
    exmap & repl,
    exmap & rev_lookup,
    lst & modifier) [static]
```

Create a symbol for replacing the expression "e" (or return a previously assigned symbol).

The symbol and expression are appended to repl, for a later application of [subs\(\)](#). An entry in the replacement table repl can be changed in some cases. If it was altered, we need to provide the modifier for the previously build expressions. The modifier is an (ordered) list, because those substitutions need to be done in the incremental order. As an example let us consider a rationalisation of the expression $e = \exp(2*x)*\cos(\exp(2*x)+1)*\exp(x)$. The first factor [GiNaC](#) denotes by something like symbol1 and will record: $e = \text{symbol1} * \cos(\text{symbol1} + 1) * \exp(x)$ $\text{repl} = \{\text{symbol1} : \exp(2*x)\}$. Similarly, the second factor would be denoted as symbol2 and we will have $e = \text{symbol1} * \text{symbol2} * \exp(x)$ $\text{repl} = \{\text{symbol1} : \exp(2*x), \text{symbol2} : \cos(\text{symbol1} + 1)\}$. Denoting the third term as symbol3 [GiNaC](#) is willing to re-think $\exp(2*x)$ as symbol3^2 rather than just symbol1. Here are two issues: 1) The replacement "symbol1 -> symbol3^2" in the previous part of the expression needs to be done outside of the present routine; 2) The pair "symbol1 : $\exp(2*x)$ " shall be deleted from the replacement table repl. However, this will create illegal substitution "symbol2 : $\cos(\text{symbol1} + 1)$ " with undefined symbol1. These both problems are mitigated through the additions of the record "symbol1==symbol3^2" to the list modifier. Changed length of the modifier signals to the calling code that the previous portion of the expression needs to be altered (it solves 1). Thus [GiNaC](#) can record now $e = \text{symbol3}^2 * \text{symbol2} * \text{symbol3}$ $\text{repl} = \{\text{symbol2} : \cos(\text{symbol1} + 1), \text{symbol3} : \exp(x)\}$ $\text{modifier} = \{\text{symbol1} == \text{symbol3}^2\}$. Then, doing the backward substitutions the list modifier will be used to restore such iterative substitutions in the right way (this solves 2).

Numeric integer quotient.

Equivalent to Maple's iquo(a,b,'r') it obeys the relation $r == a - \text{iquo}(a,b,r)*b$.

Returns

truncated quotient of a/b and remainder stored in r if both are integer, 0 otherwise.

Exceptions

<code>overflow_error</code>	(division by zero) if b is zero.

5.1.3.645 sqrt() [1/2]

```
const numeric GiNaC::sqrt (
    const numeric & x)
```

Numeric square root.

If possible, sqrt(x) should respect squares of exact numbers, i.e. sqrt(4) should return integer 2.

Parameters

<i>x</i>	numeric argument
----------	------------------

Returns

square root of *x*. Branch cut along negative real axis, the negative real axis itself where $\text{imag}(x)=0$ and $\text{real}(x)<0$ belongs to the upper part where $\text{imag}(x)>0$.

6.2.1 Detailed Description

This class is used to instantiate a global singleton object Digits which behaves just like Maple's Digits.

We need an object rather than a dumb basic type since as a side-effect we let it change `cl_default_float_format` when it gets changed. The only other meaningful thing to do with it is converting it to an unsigned, for temporarily storing its value e.g. The user must not create an own working object of this class! Since C++ forces us to make the class definition visible in order to use an object we put in a flag which prevents other objects of that class to be created.

ex GiNaC::add::thisexpairseq (
    const epvector & v,
    const ex & oc,
    bool do_index_renaming = false) const [override], [protected], [virtual]
```

Create an object of this type.

This method works similar to a constructor. It is useful because expairseq has (at least) two possible different semantics but we want to inherit methods thus avoiding code duplication. Sometimes a method in expairseq has to create a new one of the same semantics, which cannot be done by a ctor because the name (add, mul,...) is unknown on the expairseq level. In order for this trick to work a derived class must of course override this definition.

6.4.1 Detailed Description

This class holds archived versions of [GiNaC](#) expressions (class [ex](#)).

An archive can be constructed from an expression and then written to a stream; or it can be read from a stream and then unarchived, yielding back the expression. Archives can hold multiple expressions which can be referred to by name or index number. The main component of the archive class is a vector of [archive_nodes](#) which each store one object of class [basic](#) (or a derived class).

```

Test for occurrence of a pattern.

An object 'has' a pattern if it matches the pattern itself or one of the children 'has' it. As a consequence (according to the definition of children) given $e=x+y+z$, $e.has(x)$ is true but $e.has(x+y)$ is false.

6.8.3.23 match_same_type()

```
bool GiNaC::basic::match_same_type (
    const basic & other) const [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.8.3.50 compare_same_type()

```
int GiNaC::basic::compare_same_type (
    const basic & other) const [protected], [virtual]
```

Returns order relation between two objects of same type.

This needs to be implemented by each class. It may never return anything else than 0, signalling equality, or +1 and -1 signalling inequality and determining the canonical ordering. (Perl hackers will wonder why C++ doesn't feature the spaceship operator `<=>` for denoting just this.)

References [GiNaC::compare_pointers\(\)](#).

Referenced by [GiNaC::symbol::derivative\(\)](#).

6.8.3.51 is_equal_same_type()

```
bool GiNaC::basic::is_equal_same_type (
    const basic & other) const [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

6.8.3.52 calchash()

```
unsigned GiNaC::basic::calchash () const [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

6.8.3.55 `archive()`

```
void GiNaC::basic::archive (
    archive\_node & n) const [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

6.8.3.56 `read_archive()`

```
void GiNaC::basic::read_archive (
    const archive\_node & n,
    lst & syms) [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

```
ex GiNaC::basic::diff (
    const symbol & s,
    unsigned nth = 1) const
```

Default interface of nth derivative [ex::diff\(s, n\)](#).

It should be called instead of [::derivative\(s\)](#) for first derivatives and for nth derivatives it just recurses down.

Parameters

<i>s</i>	symbol to differentiate in
<i>nth</i>	order of differentiation

6.8.3.59 compare()

```

6.8.3.60 is_equal()

```
bool GiNaC::basic::is_equal (

Test for syntactic equality.

This is only a quick test, meaning objects should be in the same domain. You might have to `.expand()`, `.normal()` objects first, depending on the domain of your computation, to get a more reliable answer.

6.9.1 Detailed Description

The basic integration kernel with a logarithmic singularity at the origin.

This class represents the differential one-form

$$L_0 = \frac{d\lambda}{\lambda}$$

6.9.2 Member Function Documentation

6.9.2.1 series_coeff_impl()

```
cln::cl_N GiNaC::basic_log_kernel::series_coeff_impl (

For $\omega = d\lambda$ only the coefficient of λ^0 is non-zero.

The i-th coefficient corresponds to the power λ^{i-1} .

6.10.1 Detailed Description

```
template<class T>
class GiNaC::basic_multi_iterator< T >
```

[basic_multi_iterator](#) is a base class.

The base class itself does not do anything useful. A typical use of a class derived from [basic_multi_iterator](#) is

```
multi_iterator_ordered<int> k(0,4,2);

for( k.init(); !k.overflow(); k++) { std::cout << k << std::endl; }
```

which prints out

```
multi_iterator_ordered(0,1) multi_iterator_ordered(0,2) multi_iterator_ordered(0,3) multi_iterator_ordered(1,2)
multi_iterator_ordered(1,3) multi_iterator_ordered(2,3)
```

Individual components of k can be accessed with k[i] or k(i).

All classes derived from [basic_multi_iterator](#) follow the same syntax.

6.13.1 Detailed Description

This class holds an object representing an element of the Clifford algebra (the Dirac gamma matrices).

These objects only carry Lorentz indices. Spinor indices are hidden. A representation label (an unsigned 8-bit integer) is used to distinguish elements from different Clifford algebras (objects with different labels commute).

6.13.2 Constructor & Destructor Documentation

6.13.2.1 clifford() [1/4]

```
GiNaC::clifford::clifford (
    const ex & b,
    unsigned char rl = 0)
```

Construct object without any indices.

This constructor is for internal use only. Use the [dirac_ONE\(\)](#) function instead.

See also

[dirac_ONE](#)

6.13.2.2 clifford() [2/4]

```
GiNaC::clifford::clifford (
    const ex & b,
    const ex & mu,
    const ex & metr,
    unsigned char rl = 0,
    int comm_sign = -1)
```

Construct object with one Lorentz index.

This constructor is for internal use only. Use the [clifford_unit\(\)](#) or [dirac_gamma\(\)](#) functions instead.

See also

[dirac_gamma](#)

References [GINAC_ASSERT](#), and [GiNaC::is_a\(\)](#).

6.13.2.3 clifford() [3/4]

```
GiNaC::clifford::clifford (
    unsigned char rl,
    const ex & metr,
    int comm_sign,
    const exvector & v)
```

6.13.2.4 clifford() [4/4]

```
GiNaC::clifford::clifford (
    unsigned char rl,
    const ex & metr,
    int comm_sign,
    exvector && v)
```

6.13.3 Member Function Documentation

6.13.3.1 precedence()

```
unsigned GiNaC::clifford::precedence () const [inline], [override], [virtual]
```

Return relative operator precedence (for parenthezing output).

Reimplemented from [GiNaC::basic](#).

Referenced by [do_print_dflt\(\)](#), and [do_print_latex\(\)](#).

6.13.3.2 archive()

```
void GiNaC::clifford::archive (
    archive_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::basic](#).

References [commutator_sign](#), [metric](#), [n](#), and [representation_label](#).

6.13.3.3 read_archive()

```
void GiNaC::clifford::read_archive (
    const archive_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::basic](#).

References [commutator_sign](#), [metric](#), [n](#), and [representation_label](#).

6.13.3.4 eval_ncmul()

```
ex GiNaC::clifford::eval_ncmul (
    const exvector & v) const [override], [protected], [virtual]
```

Perform automatic simplification on noncommutative product of clifford objects.

This removes superfluous ONEs, permutes gamma5/L/R's to the front and removes squares of gamma objects.

Reimplemented from [GiNaC::basic](#).

6.13.3.5 match_same_type()

```
bool GiNaC::clifford::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.15.1 Detailed Description

This class holds a generator T_a or the unity element of the Lie algebra of $SU(3)$, as used for calculations in quantum chromodynamics.

A representation label (an unsigned 8-bit integer) is used to distinguish elements from different Lie algebras (objects with different labels commute). These objects implement an abstract representation of the group, not a specific matrix representation. The indices used for color objects should not have a variance.

6.15.2 Constructor & Destructor Documentation

6.15.2.1 `color()` [1/4]

```
GiNaC::color::color (
    const ex & b,
    unsigned char rl = 0)
```

Construct object without any color index.

This constructor is for internal use only. Use the `color_ONE()` function instead.

See also

[color_ONE](#)

Referenced by [thiscontainer\(\)](#), and [thiscontainer\(\)](#).

6.15.2.2 `color()` [2/4]

```
GiNaC::color::color (
    const ex & b,
    const ex & il,
    unsigned char rl = 0)
```

Construct object with one color index.

This constructor is for internal use only. Use the `color_T()` function instead.

See also

[color_T](#)

6.15.2.3 `color()` [3/4]

```
GiNaC::color::color (
    unsigned char rl,
    const exvector & v)
```

6.15.2.4 color() [4/4]

```
GiNaC::color::color (
    unsigned char rl,
    exvector && v)
```

6.15.3 Member Function Documentation

6.15.3.1 archive()

```
void GiNaC::color::archive (
    archive\_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::basic](#).

References [n](#), and [representation_label](#).

6.15.3.2 read_archive()

```
void GiNaC::color::read_archive (
    const archive\_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::basic](#).

References [n](#), and [representation_label](#).

6.15.3.3 eval_ncmul()

```
ex GiNaC::color::eval_ncmul (
    const exvector & v) const [override], [protected], [virtual]
```

Perform automatic simplification on noncommutative product of color objects.

This removes superfluous ONES.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::hold_ncmul\(\)](#), and [GiNaC::is_a\(\)](#).

6.15.3.4 match_same_type()

```
bool GiNaC::color::match_same_type (
    const basic & other) const \[override\], \[protected\], \[virtual\]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.15.4 Member Data Documentation

6.15.4.1 representation_label

Referenced by [archive\(\)](#), [get_representation_label\(\)](#), [match_same_type\(\)](#), [read_archive\(\)](#), [return_type_tinfo\(\)](#), [thiscontainer\(\)](#), and [thiscontainer\(\)](#).

6.23.1 Detailed Description

This class holds constants, symbols with specific numerical value.

Each object of this class must either provide their own function to evaluate it to class numeric or provide the constant as a numeric (if it's an exact number).

6.23.2 Constructor & Destructor Documentation

6.23.2.1 `constant()` [1/2]

```
GiNaC::constant::constant (
    const std::string & initname,
    evalffunctype efun = nullptr,
    const std::string & texname = std::string(),
    unsigned domain = domain::complex)
```

References [GiNaC::status_flags::evaluated](#), [GiNaC::status_flags::expanded](#), [name](#), [GiNaC::basic::setflag\(\)](#), and [TeX_name](#).

6.23.2.2 `constant()` [2/2]

```
GiNaC::constant::constant (
    const std::string & initname,
    const numeric & initnumber,
    const std::string & texname = std::string(),
    unsigned domain = domain::complex)
```

6.23.3 Member Function Documentation

6.23.3.1 `info()`

```
bool GiNaC::constant::info (
    unsigned inf) const [override], [virtual]
```

Information about the object.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::domain::positive](#), and [GiNaC::domain::real](#).

6.23.3.7 archive()

```
void GiNaC::constant::archive (
    archive_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::basic](#).

References [n](#), and [name](#).

6.23.3.8 read_archive()

```
void GiNaC::constant::read_archive (
    const archive_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::Catalan](#), [GiNaC::Euler](#), [n](#), [name](#), and [GiNaC::Pi](#).

6.23.3.9 derivative()

```
ex GiNaC::constant::derivative (
    const symbol & s) const [override], [protected], [virtual]
```

Implementation of [ex::diff\(\)](#) for a constant always returns 0.

See also

[ex::diff](#)

Reimplemented from [GiNaC::basic](#).

References [GiNaC::_ex0](#).

6.23.3.10 is_equal_same_type()

```
bool GiNaC::constant::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

6.23.3.11 calchash()

```
unsigned GiNaC::constant::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

6.24.4.15 `is_equal_same_type()`

```
template<template< class T, class=std::allocator< T > > class C>
bool GiNaC::container< C >::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls `compare_same_type()`. The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

Reimplemented from `GiNaC::basic`.

Reimplemented in `GiNaC::fderivative`, and `GiNaC::function`.

Enumerator

automatic	Let the system choose. A heuristics is applied for automatic determination of a suitable algorithm.
gauss	<p>Gauss elimination. If $m_{i,j}^{(0)}$ are the entries of the original matrix, then the matrix is transformed into triangular form by applying the rules</p> $m_{i,j}^{(k+1)} = m_{i,j}^{(k)} - m_{i,k}^{(k)} m_{k,j}^{(k)} / m_{k,k}^{(k)}$ <p>The determinant is then just the product of diagonal elements. Choose this algorithm only for purely numerical matrices.</p>
divfree	<p>Division-free elimination. This is a modification of Gauss elimination where the division by the pivot element is not carried out. If $m_{i,j}^{(0)}$ are the entries of the original matrix, then the matrix is transformed into triangular form by applying the rules</p> $m_{i,j}^{(k+1)} = m_{i,j}^{(k)} m_{k,k}^{(k)} - m_{i,k}^{(k)} m_{k,j}^{(k)}$ <p>The determinant can later be computed by inspecting the diagonal elements only. This algorithm is only there for the purpose of cross-checks. It is never fast.</p>
laplace	Laplace elimination. This is plain recursive elimination along minors although multiple minors are avoided by the algorithm. Although the algorithm is exponential in complexity it is frequently the fastest one when the matrix is populated by complicated symbolic expressions.
bareiss	<p>Bareiss fraction-free elimination. This is a modification of Gauss elimination where the division by the pivot element is <i>delayed</i> until it can be carried out without computing GCDs. If $m_{i,j}^{(0)}$ are the entries of the original matrix, then the matrix is transformed into triangular form by applying the rules</p> $m_{i,j}^{(k+1)} = (m_{i,j}^{(k)} m_{k,k}^{(k)} - m_{i,k}^{(k)} m_{k,j}^{(k)}) / m_{k-1,k-1}^{(k-1)}$ <p>(We have set $m_{-1,-1}^{(-1)} = 1$ in order to avoid a case distinction in above formula.) It can be shown that nothing more than polynomial long division is needed for carrying out the division. The determinant can then be read off from the lower right entry. This algorithm is rarely fast for computing determinants.</p>

6.38.1 Detailed Description

The kernel corresponding to the Eisenstein series $h_{k,N,r,s}(\tau)$.

This class represents the differential one-form

$$\omega_{k,N,r,s}^{\text{Eisenstein,h}} = C_k h_{k,N,r,s}(\tau) \frac{d\bar{q}_N}{\bar{q}_N}$$

6.38.2 Constructor & Destructor Documentation

```
ex GiNaC::Eisenstein_h_kernel::series (
    const relational & r,
    int order,

6.39.1 Detailed Description

The kernel corresponding to the Eisenstein series $E_{k,N,a,b,K}(\tau)$.

This class represents the differential one-form

$$\omega_{k,N,a,b,K}^{\text{Eisenstein}} = C_k E_{k,N,a,b,K}(\tau) \frac{d\bar{q}_N}{\bar{q}_N}$$

The integers a and b are either one or the discriminant of a quadratic number field. This class represents Eisenstein series, which can be defined by primitive Dirichlet characters from the Kronecker symbol. This implies that the characters take the values -1,0,1, i.e. no higher roots of unity occur. The

$$\bar{q}$$

-expansion has then rational coefficients.

```
ex GiNaC::Eisenstein_kernel::series (
    const relational & r,

6.48.1 Detailed Description

Lightweight wrapper for [GiNaC](#)'s symbolic objects.

It holds a pointer to the other object in order to do garbage collection by the method of reference counting. I.e., it is a smart pointer. Also, the constructor [ex::ex\(const basic & other\)](#) calls the methods that do automatic evaluation. E.g., x-x turns automatically into 0.

```
GiNaC::ex::ex (
    const std::string & s,
    const ex & l) [inline]
```

Construct `ex` from string and a list of symbols.

The input grammar is similar to the [GiNaC](#) output format. All symbols and indices to be used in the expression must be specified in a list in the second argument. Undefined symbols and other parser errors will throw an exception.

6.48.3.52 normal()

```
ex GiNaC::ex::normal () const
```

Normalization of rational functions.

This function converts an expression to its normal form "numerator/denominator", where numerator and denominator are (relatively prime) polynomials. Any subexpressions which are not rational functions (like non-rational numbers, non-integer powers or functions like [sin\(\)](#), [cos\(\)](#) etc.) are replaced by temporary symbols which are re-substituted by the (normalized) subexpressions before [normal\(\)](#) returns (this way, any expression can be treated as a rational function). [normal\(\)](#) is applied recursively to arguments of functions etc.

Returns

normalized expression

6.48.3.53 to_rational()

```
ex GiNaC::ex::to_rational (
    exmap & repl) const
```

Rationalization of non-rational functions.

This function converts a general expression to a rational function by replacing all non-rational subexpressions (like non-rational numbers, non-integer powers or functions like [sin\(\)](#), [cos\(\)](#) etc.) to temporary symbols. This makes it possible to use functions like [gcd\(\)](#) and [divide\(\)](#) on non-rational functions by applying [to_rational\(\)](#) on the arguments, calling the desired function and re-substituting the temporary symbols in the result. To make the last step possible, all temporary symbols and their associated expressions are collected in the map specified by the repl parameter, ready to be passed as an argument to [ex::subs\(\)](#).

Parameters

<i>repl</i>	collects all temporary symbols and their replacements

6.48.4.2 are_ex_trivially_equal

```
bool are_ex_trivially_equal (
    const ex & e1,
    const ex & e2) [friend]
```

Compare two objects of class quickly without doing a deep tree traversal.

Returns

"true" if they are equal "false" if equality cannot be established quickly (e1 and e2 may still be equal, in this case).

6.48.4.3 ex_to

```
template<class T >
const T & ex_to (
    const ex & e) [friend]
```

Return a reference to the basic-derived class T object embedded in an expression.

This is fast but unsafe: the result is undefined if the expression does not contain a T object at its top level. Hence, you should generally check the type of e first. Also, you shouldn't cache the returned reference because GiNaC's garbage collector may destroy the referenced object any time it's used in another expression.

Parameters

e	expression
---	------------

Returns

reference to object of class T

- [ex coeff](#)

6.53.1 Detailed Description

A pair of expressions.

This is similar to STL's `pair<>`. It is slightly extended since we need to account for methods like [.compare\(\)](#). Also, since this is meant for use by class `expairseq` it must satisfy the invariance that the member `coeff` must be of type `numeric`.

6.57.1 Detailed Description

A sequence of class `expair`.

This is used for time-critical classes like sums and products of terms since handling a list of `coeff` and `rest` is much faster than handling a list of products or powers, respectively. (Not incidentally, Maple does it the same way, maybe others too.) The semantics is (at least) twofold: one for addition and one for multiplication and several methods have to be overridden by derived classes to reflect the change in semantics. However, most functionality turns out to be shared between addition and multiplication, which is the reason why there is this base class.

6.57.3.12 archive()

```
void GiNaC::expairseq::archive (
    archive_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::basic](#).

References [n](#), [overall_coeff](#), and [seq](#).

6.57.3.13 read_archive()

```
void GiNaC::expairseq::read_archive (
    const archive_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::basic](#).

6.57.3.14 is_equal_same_type()

```
bool GiNaC::expairseq::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

6.57.3.16 calchash()

```
unsigned GiNaC::expairseq::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

6.57.3.17 expand()

```
ex GiNaC::expairseq::expand (
    unsigned options = 0) const [override], [protected], [virtual]
```

multiply it out and return the result as a new expression.

Reimplemented from [GiNaC::basic](#).

Reimplemented in [GiNaC::mul](#).

6.57.3.18 thisexpairseq() [1/2]

```
ex GiNaC::expairseq::thisexpairseq (
    const epvector & v,
    const ex & oc,
    bool do_index_renaming = false) const [protected], [virtual]
```

Create an object of this type.

This method works similar to a constructor. It is useful because expairseq has (at least) two possible different semantics but we want to inherit methods thus avoiding code duplication. Sometimes a method in expairseq has to create a new one of the same semantics, which cannot be done by a ctor because the name (add, mul,...) is unknown on the expairseq level. In order for this trick to work a derived class must of course override this definition.

6.62.1 Detailed Description

This class represents the (abstract) derivative of a symbolic function.

It is used to represent the derivatives of functions that do not have a derivative or series expansion procedure defined.

6.62.2 Constructor & Destructor Documentation

6.62.2.1 `fderivative()` [1/3]

```
GiNaC::fderivative::fderivative (
    unsigned ser,
    unsigned param,
    const exvector & args)
```

Construct derivative with respect to one parameter.

Parameters

<i>ser</i>	Serial number of function
<i>param</i>	Number of parameter with respect to which to take the derivative
<i>args</i>	Arguments of derivative function

References [parameter_set](#).

Referenced by [derivative\(\)](#), [thiscontainer\(\)](#), and [thiscontainer\(\)](#).

6.62.2.2 `fderivative()` [2/3]

```
GiNaC::fderivative::fderivative (
    unsigned ser,
    const paramset & params,
    const exvector & args)
```

Construct derivative with respect to multiple parameters.

Parameters

<i>ser</i>	Serial number of function
<i>params</i>	Set of numbers of parameters with respect to which to take the derivative
<i>args</i>	Arguments of derivative function

6.62.2.3 fderivative() [3/3]

```
GiNaC::fderivative::fderivative (
    unsigned ser,
    const paramset & params,
    exvector && v)
```

6.62.3 Member Function Documentation**6.62.3.1 print()**

```
void GiNaC::fderivative::print (
    const print_context & c,
    unsigned level = 0) const [override], [virtual]
```

Output to stream.

This performs double dispatch on the dynamic type of *this and the dynamic type of the supplied print context.

Parameters

<i>c</i>	print context object that describes the output formatting
<i>level</i>	value that is used to identify the precedence or indentation level for placing parentheses and formatting

Reimplemented from [GiNaC::basic](#).

References [c](#), and [GiNaC::basic::print\(\)](#).

6.62.3.2 eval()

```
ex GiNaC::fderivative::eval () const [override], [virtual]
```

Perform automatic non-interruptive term rewriting rules.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::function::function\(\)](#), [GiNaC::basic::hold\(\)](#), [parameter_set](#), [GiNaC::function::pderivative\(\)](#), [GiNaC::function::registered_functions\(\)](#), [GiNaC::container_storage< C >::seq](#), and [GiNaC::function::serial](#).

6.62.3.3 series()

```
ex GiNaC::fderivative::series (
    const relational & r,
    int order,
    unsigned options = 0) const [override], [virtual]
```

The series expansion of derivatives falls back to Taylor expansion.

6.62.3.4 thiscontainer() [1/2]

```
ex GiNaC::fderivative::thiscontainer (
    const exvector & v) const [override]
```

References [fderivative\(\)](#), [parameter_set](#), and [GiNaC::function::serial](#).

6.62.3.5 thiscontainer() [2/2]

```

    exvector && v) const [override]
```

References [fderivative\(\)](#), [parameter_set](#), and [GiNaC::function::serial](#).

6.62.3.6 archive()

```
void GiNaC::fderivative::archive (
    archive_node & n) const [override], [virtual]
```

Archive the object.

Reimplemented from [GiNaC::container< class >](#).

References [GiNaC::container< class >::end\(\)](#), [n](#), and [parameter_set](#).

6.62.3.7 read_archive()

```
void GiNaC::fderivative::read_archive (
    const archive\_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::container< class >](#).

References [n](#), and [parameter_set](#).

6.62.3.8 derivative()

```
ex GiNaC::fderivative::derivative (
    const symbol & s) const [override], [protected], [virtual]
```

Implementation of [ex::diff\(\)](#) for derivatives.

It applies the chain rule.

See also

[ex::diff](#)

Reimplemented from [GiNaC::basic](#).

References [GiNaC::ex::diff\(\)](#), [fderivative\(\)](#), [GiNaC::ex::is_zero\(\)](#), [parameter_set](#), [GiNaC::container_storage< C >::seq](#), and [GiNaC::function::serial](#).

6.62.3.9 is_equal_same_type()

```
bool GiNaC::fderivative::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

Reimplemented from [GiNaC::container< class >](#).

References [GINAC_ASSERT](#), [GiNaC::is_a\(\)](#), and [parameter_set](#).

6.62.3.10 `match_same_type()`

```
bool GiNaC::fderivative::match_same_type (
    const basic & other) const \[override\], \[protected\], \[virtual\]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

[basic::match](#)

Reimplemented from [GiNaC::basic](#).

References [GINAC_ASSERT](#), [GiNaC::is_a\(\)](#), and [parameter_set](#).

6.62.3.11 `derivatives()`

```
const paramset & GiNaC::fderivative::derivatives () const
```

Expose this object's derivative structure.

Parameter numbers occurring more than once stand for repeated differentiation with respect to that parameter. If a symbolic function $f(x,y)$ is differentiated with respect to x , this method will return $\{0\}$. If $f(x,y)$ is differentiated twice with respect to y , it will return $\{1,1\}$. (This corresponds to the way this object is printed.)

Returns

multiset of function's parameter numbers that are abstractly differentiated.

    const print\_context & c,

```

```
void GiNaC::function::print (

This performs double dispatch on the dynamic type of **this* and the dynamic type of the supplied print context.

Parameters

<i>c</i>	print context object that describes the output formatting
<i>level</i>	value that is used to identify the precedence or indentation level for placing parentheses and formatting

```

This method is defined to be in line with behavior of [function::return_type\(\)](#)

Reimplemented from [GiNaC::basic](#).

References [GiNaC::ex::begin\(\)](#), and [GiNaC::container_storage< C >::seq](#).

6.63.3.7 calchash()

```
unsigned GiNaC::function::calchash () const [override], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

6.63.3.17 derivative()

```
ex GiNaC::function::derivative (
    const symbol & s) const [override], [protected], [virtual]
```

Implementation of [ex::diff\(\)](#) for functions.

It applies the chain rule, except for the Order term function. @see [ex::diff](#)

Reimplemented from [GiNaC::basic](#).

References [GiNaC::ex::diff\(\)](#), [expl_derivative\(\)](#), [GiNaC::ex::is_zero\(\)](#), [pderivative\(\)](#), and [GiNaC::container_storage< C >::seq](#).

6.63.3.18 is_equal_same_type()

```
bool GiNaC::function::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

Reimplemented from [GiNaC::container< class >](#).

References [GINAC_ASSERT](#), [GiNaC::is_a\(\)](#), [GiNaC::container< class >::is_equal_same_type\(\)](#), and [serial](#).

6.63.3.19 match_same_type()

```
bool GiNaC::function::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

no_heur_gcd	Usually GiNaC tries heuristic GCD first, because typically it's much faster than anything else. Even if heuristic algorithm fails, the overhead is negligible w.r.t. cost of computing the GCD by some other method. However, some people dislike it, so here's a flag which tells GiNaC to NOT use the heuristic algorithm.
no_part_factored	GiNaC tries to avoid expanding expressions when computing GCDs. This is a good idea, but some people dislike it. Hence the flag to disable special handling of partially factored polynomials. DON'T SET THIS unless you <i>really</i> know what are you doing!
use_sr_gcd	By default GiNaC uses modular GCD algorithm. Typically it's much faster than PRS (pseudo remainder sequence) algorithm. This flag forces GiNaC to use PRS algorithm

6.72.1 Detailed Description

This class holds one index of an indexed object.

Indices can theoretically consist of any symbolic expression but they are usually only just a symbol (e.g. "mu", "i") or numeric (integer). Indices belong to a space with a certain numeric or symbolic dimension.

6.72.2 Constructor & Destructor Documentation

<i>dim</i>	Dimension of index space (numeric or symbolic)

6.72.3.5 evalf()

```

By default, [basic::evalf](#) would evaluate the index value but we don't want a.1 to become a.

(1.0).

6.72.3.6 subs()

```
ex GiNaC::idx::subs (

```

Substitute a set of objects by arbitrary expressions.

The ex returned will already be evaluated.

```
void GiNaC::idx::archive (
    archive_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::basic](#).

Reimplemented in [GiNaC::spinidx](#), and [GiNaC::varidx](#).

References [dim](#), [n](#), and [value](#).

6.72.3.8 read_archive()

```
void GiNaC::idx::read_archive (
    const archive_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

6.72.3.9 derivative()

```
ex GiNaC::idx::derivative (
    const symbol & s) const [override], [protected], [virtual]
```

Implementation of [ex::diff\(\)](#) for an index always returns 0.

[ex::diff](#)

6.72.3.10 `match_same_type()`

```
bool GiNaC::idx::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.72.3.11 `calchash()`

```
unsigned GiNaC::idx::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class [basic](#) computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

The method `series_coeff_impl` can be used, if a single coefficient can be computed independently of the others.

The method `Laurent_series` can be used, if it is more efficient to compute a Laurent series in one shot and to determine a range of coefficients from this Laurent series.

6.86.1 Detailed Description

Helper class to initialize the library.

There must be one static object of this class in every object file that makes use of our flyweights in order to guarantee proper initialization. Hence we put it into this file which is included by every relevant file anyways. This is modeled after section [jos::Init] of the C++ standard, where cout and friends are set up.

Class to handle the renaming of dummy indices.

It holds a vector of indices that are being used in the expression so far. If the same index occurs again as a dummy index in a factor, it is to be renamed. Unless dummy index renaming was switched off, of course ;-)

deserialize) object from archive.

Reimplemented from [GiNaC::basic](#).

6.89.3.15 match_same_type()

```
bool GiNaC::matrix::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.89.3.29 determinant()

```
ex GiNaC::matrix::determinant (
    unsigned algo = determinant\_algo::automatic) const
```

Determinant of square matrix.

This routine doesn't actually calculate the determinant, it only implements some heuristics about which algorithm to run. If all the elements of the matrix are elements of an integral domain the determinant is also in that integral domain and the result is expanded only. If one or more elements are from a quotient field the determinant is usually also in that quotient field and the result is normalized before it is returned. This implies that the determinant of the symbolic 2x2 matrix $\begin{bmatrix} a/(a-b) & 1 \\ b/(a-b) & 1 \end{bmatrix}$ is returned as unity. (In this respect, it behaves like MapleV and unlike Mathematica.)

Parameters

<i>algo</i>	allows to chose an algorithm
-------------	------------------------------

Returns

the determinant as a new expression

Exceptions

<i>logic_error</i>	(matrix not square)
--------------------	---------------------

6.89.3.30 trace()

```
ex GiNaC::matrix::trace () const
```

Trace of a matrix.

The result is normalized if it is in some quotient field and expanded only otherwise. This implies that the trace of the symbolic 2x2 matrix $\begin{bmatrix} a/(a-b), x \\ y, b/(b-a) \end{bmatrix}$ is recognized to be unity.

Returns

the sum of diagonal elements

Exceptions

<i>logic_error</i>	(matrix not square)

6.89.3.31 charpoly()

```
ex GiNaC::matrix::charpoly (
    const ex & lambda) const
```

Characteristic Polynomial.

Following mathematica notation the characteristic polynomial of a matrix M is defined as the determinant of (M - lambda * 1) where 1 stands for the unit matrix of the same dimension as M. Note that some CASs define it with a sign inside the determinant which gives rise to an overall sign if the dimension is odd. This method returns the characteristic polynomial collected in powers of lambda as a new expression.

Returns

characteristic polynomial as new expression

Exceptions

<i>logic_error</i>	(matrix not square)
--------------------	---------------------

Returns

n x p solution matrix

Exceptions

<i>invalid_argument</i>	(1st argument must be matrix of symbols)
<i>runtime_error</i>	(inconsistent linear system)

6.89.3.38 determinant_minor()

```
ex GiNaC::matrix::determinant_minor () const [protected]
```

Recursive determinant for small matrices having at least one symbolic entry.

The basic algorithm, known as Laplace-expansion, is enhanced by some bookkeeping to avoid calculation of the same submatrices ("minors") more than once. According to W.M.Gentleman and S.C.Johnson this algorithm is better than elimination schemes for matrices of sparse multivariate polynomials and also for matrices of dense univariate polynomials if the matrix' dimension is larger than 7.

Returns

the determinant as a new expression (in expanded form)

The algorithm is ok for matrices with numeric coefficients but quite unsuited for symbolic matrices.

Parameters

<i>det</i>	may be set to true to save a lot of space if one is only interested in the diagonal elements (i.e. for calculating determinants). The others are set to zero in this case.

6.89.3.41 division_free_elimination()

```
int GiNaC::matrix::division_free_elimination (
    const bool det = false) [protected]
```

Perform the steps of division free elimination to bring the $m \times n$ matrix into an upper echelon form.

Parameters

<i>det</i>	may be set to true to save a lot of space if one is only interested in the diagonal elements (i.e. for calculating determinants). The others are set to zero in this case.
------------	--

Returns

sign is 1 if an even number of rows was swapped, -1 if an odd number of rows was swapped and 0 if the matrix is singular.

6.89.3.42 fraction_free_elimination()

```
int GiNaC::matrix::fraction_free_elimination (
    const bool det = false) [protected]
```

Perform the steps of Bareiss' one-step fraction free elimination to bring the matrix into an upper echelon form.

Fraction free elimination means that divide is used straightforwardly, without computing GCDs first. This is possible, since we know the divisor at each step.

Parameters

<i>det</i>	may be set to true to save a lot of space if one is only interested in the last element (i.e. for calculating determinants). The others are set to zero in this case.
------------	---

Returns

sign is 1 if an even number of rows was swapped, -1 if an odd number of rows was swapped and 0 if the matrix is singular.

6.89.3.44 pivot()

```
int GiNaC::matrix::pivot (
    unsigned ro,
    unsigned co,
    bool symbolic = true) [protected]
```

Partial pivoting method for matrix elimination schemes.

Usual pivoting (`symbolic==false`) returns the index to the element with the largest absolute value in column `ro` and swaps the current row with the one where the element was found. With (`symbolic==true`) it does the same thing with the first non-zero element.

Parameters

<i>ro</i>	is the row from where to begin
<i>co</i>	is the column to be inspected
<i>symbolic</i>	signal if we want the first non-zero element to be pivoted (true) or the one with the largest absolute value (false).

Returns

0 if no interchange occurred, -1 if all are zero (usually signaling a degeneracy) and positive integer `k` means that rows `ro` and `k` were swapped.

6.91.1 Detailed Description

A kernel corresponding to a polynomial in Eisenstein series.

This class represents the differential one-form

$$\omega^{\text{modular}}(P_k(\eta_{k_1}^{(1)}, \dots, \eta_{k_r}^{(r)})) = C_k P_k(\eta_{k_1}^{(1)}, \dots, \eta_{k_r}^{(r)}) \frac{d\bar{q}_N}{\bar{q}_N}.$$

ex GiNaC::mul::thisexpairseq (
    const epvector & v,
    const ex & oc,
    bool do_index_renaming = false) const [override], [protected], [virtual]
```

Create an object of this type.

This method works similar to a constructor. It is useful because expairseq has (at least) two possible different semantics but we want to inherit methods thus avoiding code duplication. Sometimes a method in expairseq has to create a new one of the same semantics, which cannot be done by a ctor because the name (add, mul,...) is unknown on the expairseq level. In order for this trick to work a derived class must of course override this definition.

6.99.1 Detailed Description

```
template<class T>
class GiNaC::multi_iterator_permutation< T >
```

The class `multi_iterator_permutation` defines a multi_iterator (i_1, i_2, \dots, i_k) , for which.

$$B \leq i_j < N$$

and

$$i_i \neq i_j$$

In particular, if $N - B = k$, `multi_iterator_permutation` loops over all permutations of k elements.

6.102.1 Detailed Description

The integration kernel for multiple polylogarithms.

This class represents the differential one-form

$$\omega^{\text{mpl}}(z) = \frac{d\lambda}{\lambda - z}$$

For the case $z = 0$ the class `basic_log_kernel` should be used.

6.105.3.7 has()

```
bool GiNaC::numeric::has (
    const ex & other,
    unsigned options = 0) const [override], [virtual]
```

Disassemble real part and imaginary part to scan for the occurrence of a single number.

Also handles the imaginary unit. It ignores the sign on both this and the argument, which may lead to what might appear as funny results: $(2+i).has(-2) \rightarrow true$. But this is consistent, since we also would like to have $(-2+i).has(2) \rightarrow true$ and we want to think about the sign as a multiplicative factor.

Reimplemented from [GiNaC::basic](#).

ex GiNaC::numeric::eval () const [override], [virtual]
```

References [GiNaC::basic::hold\(\)](#).

6.105.3.9 evalf()

```
ex GiNaC::numeric::evalf () const [override], [virtual]
```

Cast numeric into a floating-point object.

For example `exact.numeric(1)` is returned as a `1.00000000000000000000` and so on according to how Digits is currently set. In case the object already was a floating point number the precision is trimmed to match the currently set default.

Returns

an ex-handle to a numeric.

References [numeric\(\)](#), and [value](#).

6.105.3.10 subs()

```
ex GiNaC::numeric::subs (

```

Substitute a set of objects by arbitrary expressions.

The ex returned will already be evaluated.

ex GiNaC::numeric::normal (
    exmap & repl,
    exmap & rev_lookup,
    lst & modifier) const [override], [virtual]

6.105.3.23 is_equal_same_type()

```
bool GiNaC::numeric::is_equal_same_type (
    const basic & other) const \[override\], \[protected\], \[virtual\]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

6.105.3.24 calchash()

```
unsigned GiNaC::numeric::calchash () const \[override\], \[protected\], \[virtual\]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

6.119.3.10 eval()

```
ex GiNaC::power::eval () const [override], [virtual]
```

Perform automatic term rewriting rules in this class.

In the following x, x_1, x_2, \dots stand for a symbolic variables of type `ex` and c, c_1, c_2, \dots stand for such expressions that contain a plain number.

- $x^0 \rightarrow 1$ (also handles 0^0)
- $x^1 \rightarrow x$
- $0^c \rightarrow 0$ or exception (depending on the real part of c)
- $1^x \rightarrow 1$
- $c_1^{c_2} \rightarrow c_1^{n_1} c_1^{c_2-n_1}$ (so that $0 < (c_2-n_1) < 1$, try to evaluate roots, possibly in numerator and denominator of c_1)
- $x^{(x, c_1), c_2} \rightarrow x^{(x, c_1 c_2)}$ if x is positive and c_1 is real.
- $x^{(x, c_1), c_2} \rightarrow x^{(x, c_1 c_2)}$ (c_2 integer or $-1 < c_1 \leq 1$ or ($c_1 = -1$ and $c_2 > 0$), case $c_1 = 1$ should not happen, see below!)
- $x^{(x, y, z), c} \rightarrow x^{(x^c y^c z^c)}$ (if c integer)
- $x^{(x, c_1), c_2} \rightarrow x^{(x, c_2)} c_1^{c_2}$ ($c_1 > 0$)
- $x^{(x, c_1), c_2} \rightarrow x^{(-x, c_2)} c_1^{c_2}$ ($c_1 < 0$)

6.127.1 Detailed Description

This class represents a print method for a certain algebraic class and [print_context](#) type.

Its main purpose is to hide the difference between member functions and nonmember functions behind one unified [operator\(\)](#) interface. [print_functor](#) has value semantics and acts as a smart pointer (with deep copy) to a class derived from [print_functor_impl](#) which implements the actual function call.

6.138.1 Detailed Description

This class holds a extended truncated power series (positive and negative integer powers).

It consists of expression coefficients (only non-zero coefficients are stored), an expansion variable and an expansion point. Other classes must provide members to convert into this type.

6.138.2 Constructor & Destructor Documentation

6.138.2.1 `pseries()` [1/2]

```
GiNaC::pseries::pseries (
    const ex & rel_,
    const epvector & ops_)
```

Construct `pseries` from a vector of coefficients and powers.

`expair.rest` holds the coefficient, `expair.coeff` holds the power. The powers must be integers (positive or negative) and in ascending order; the last coefficient can be `Order(_ex1)` to represent a truncated, non-terminating series.

Parameters

<i>rel</i> ↔ —	expansion variable and point (must hold a relational)
<i>ops</i> ↔ —	vector of {coefficient, power} pairs (coefficient must not be zero)

6.138.3 Member Function Documentation**6.138.3.1 precedence()**

```

Referenced by [print_series\(\)](#).

6.138.3.2 nops()

```
size_t GiNaC::pseries::nops () const [override], [virtual]
```

Return the number of operands including a possible order term.

Reimplemented from [GiNaC::basic](#).

References [seq](#).

Referenced by [coeffop\(\)](#), [exponop\(\)](#), and [GiNaC::log_series\(\)](#).

6.138.3.3 op()

```
ex GiNaC::pseries::op (

```

Return the ith term in the series when represented as a sum.

Reimplemented from [GiNaC::basic](#).

References [coeff\(\)](#), [GiNaC::is_order_function\(\)](#), [point](#), [GiNaC::pow\(\)](#), [seq](#), and [var](#).

6.138.3.4 degree()

```
int GiNaC::pseries::degree (
    const ex & s) const [override], [virtual]
```

Return degree of highest power of the series.

This is usually the exponent of the Order term. If s is not the expansion variable of the series, the series is examined termwise.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::ex_to\(\)](#), [GiNaC::ex::is_equal\(\)](#), [seq](#), and [var](#).

6.138.3.5 ldegree()

```
int GiNaC::pseries::ldegree (
    const ex & s) const [override], [virtual]
```

Return degree of lowest power of the series.

This is usually the exponent of the leading term. If s is not the expansion variable of the series, the series is examined termwise. If s is the expansion variable but the expansion point is not zero the series is not expanded to find the degree. I.e.: $(1-x) + (1-x)^2 + \text{Order}((1-x)^3)$ has `ldegree(x)` 1, not 0.

Reimplemented from [GiNaC::basic](#).

Referenced by [GiNaC::log_series\(\)](#), [mul_series\(\)](#), and [power_const\(\)](#).

6.138.3.6 coeff()

```
ex GiNaC::pseries::coeff (
    const ex & s,
    int n = 1) const [override], [virtual]
```

Return coefficient of degree n in power series if s is the expansion variable.

If the expansion point is nonzero, by definition the n=1 coefficient in s of $a+b*(s-z)+c*(s-z)^2+\text{Order}((s-z)^3)$ is b (assuming the expansion took place in the s in the first place). If s is not the expansion variable, an attempt is made to convert the series to a polynomial and return the corresponding coefficient from there.

Reimplemented from [GiNaC::basic](#).

6.138.3.7 collect()

```
ex GiNaC::pseries::collect (
    const ex & s,
    bool distributed = false) const [override], [virtual]
```

Does nothing.

Reimplemented from [GiNaC::basic](#).

6.138.3.8 eval()

6.145.5.11 match_same_type()

```
bool GiNaC::relational::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.145.5.14 calchash()

```
unsigned GiNaC::relational::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

6.147.1 Detailed Description

The remember table is organized like an n-fold associative cache in a microprocessor.

The table has a width of 's' (which is rounded to `table_size`, some power of 2 near 's', internally) and a depth of 'as' (unless you choose that entries are never discarded). The place where an entry is stored depends on the hashvalue of the parameters of the function (this corresponds to the address of byte to be cached). The '`log_2(table_size)`' least significant bits of this hashvalue give the slot in which the entry will be stored or looked up. Each slot can take up to 'as' entries. If a slot is full, an older entry is removed by one of the following strategies:

- oldest entry (the first one in the list)
- least recently used (the one with the lowest 'last_access')
- least frequently used (the one with the lowest 'successful_hits') or all entries are kept which means that the table grows indefinitely.

6.156.1 Detailed Description

This class holds a spinor index that can be dotted or undotted and that also has a variance.

This is used in the Weyl-van-der-Waerden formalism where the dot indicates complex conjugation. There is an associated (asymmetric) metric tensor that can be used to raise/lower spinor indices.

6.156.2 Constructor & Destructor Documentation

6.156.2.1 `spinidx()`

```
GiNaC::spinidx::spinidx (
    const ex & v,
    const ex & dim = 2,
    bool covariant = false,
    bool dotted = false)
```

Construct index with given value, dimension, variance and dot.

Parameters

<code>v</code>	Value of index (numeric or symbolic)
<code>dim</code>	Dimension of index space (numeric or symbolic)
<code>covariant</code>	Make covariant index (default is contravariant)
<code>dotted</code>	Make covariant dotted (default is undotted)

6.156.3 Member Function Documentation

6.156.3.1 is_dummy_pair_same_type()

```
bool GiNaC::spinidx::is_dummy_pair_same_type (
    const basic & other) const [override], [virtual]
```

Check whether the index forms a dummy index pair with another index of the same type.

Reimplemented from [GiNaC::idx](#).

References [dotted](#).

6.156.3.2 conjugate()

```
ex GiNaC::spinidx::conjugate () const [inline], [override], [virtual]

6.156.3.3 archive()

```
void GiNaC::spinidx::archive (
    archive\_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::idx](#).

References [dotted](#), and [n](#).

6.156.3.4 read_archive()

```
void GiNaC::spinidx::read_archive (
    const archive\_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::idx](#).

References [dotted](#), and [n](#).

6.156.3.5 match_same_type()

```
bool GiNaC::spinidx::match_same_type (
    const basic & other) const    [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.157.1 Detailed Description

This class represents an antisymmetric spinor metric tensor which can be used to raise/lower indices of 2-component Weyl spinors.

If indexed, it must have exactly two indices of the same type which must be of class `spinidx` or a subclass and have dimension 2.

Test for occurrence of a pattern.

An object 'has' a pattern if it matches the pattern itself or one of the children 'has' it. As a consequence (according to the definition of children) given $e=x+y+z$, $e.has(x)$ is true but $e.has(x+y)$ is false.

6.160.3.17 match()

Reimplemented from [GiNaC::basic](#).

6.160.3.18 match_same_type()

```
template<class T , template< class > class ComparisonPolicy>
bool GiNaC::structure< T, ComparisonPolicy >::match_same_type (
    const basic & other) const [inline], [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.160.3.37 contract_with()

    exvector::iterator other,
    exvector & v) const [inline], [override], [virtual]
```

Try to contract two indexed expressions that appear in the same product.

If a contraction exists, the function overwrites one or both of the expressions and returns true. Otherwise it returns false. It is guaranteed that both expressions are of class indexed (or a subclass) and that at least one dummy index has been found. This functions is used internally by [simplify_indexed\(\)](#).

Parameters

<i>self</i>	Pointer to first indexed expression; its base object is *this
<i>other</i>	Pointer to second indexed expression
<i>v</i>	The complete vector of factors

Returns

true if the contraction was successful, false otherwise

6.160.3.40 is_equal_same_type()

```
template<class T , template< class > class ComparisonPolicy>
bool GiNaC::structure< T, ComparisonPolicy >::is_equal_same_type (
    const basic & other) const [inline], [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

Reimplemented from [GiNaC::basic](#).

References [GINAC_ASSERT](#), [GiNaC::is_a\(\)](#), and [GiNaC::structure< T, ComparisonPolicy >::obj](#).

6.160.3.41 calchash()

```
template<class T , template< class > class ComparisonPolicy>
unsigned GiNaC::structure< T, ComparisonPolicy >::calchash () const [inline], [override],
[protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class `basic` computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

6.169.3.16 is_equal_same_type()

```
bool GiNaC::symbol::is_equal_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if two objects of same type are equal.

Normally needs not be reimplemented as long as it wasn't overwritten by some parent class, since it just calls [compare_same_type\(\)](#). The reason why this function exists is that sometimes it is easier to determine equality than an order relation and then it can be overridden.

Reimplemented from [GiNaC::basic](#).

References [GINAC_ASSERT](#), [GiNaC::is_a\(\)](#), and [serial](#).

Referenced by [series\(\)](#).

6.169.3.17 calchash()

```
unsigned GiNaC::symbol::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class `basic` computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

References [GiNaC::golden_ratio_hash\(\)](#), [GiNaC::status_flags::hash_calculated](#), [GiNaC::basic::hashvalue](#), [GiNaC::make_hash_seed\(\)](#), [serial](#), and [GiNaC::basic::setflag\(\)](#).

```

6.171.4.3 calchash()

```
unsigned GiNaC::symmetry::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

Reimplemented from [GiNaC::basic](#).

References [children](#), [GiNaC::status_flags::evaluated](#), [GiNaC::basic::flags](#), [GiNaC::status_flags::hash_calculated](#), [GiNaC::basic::hashvalue](#), [indices](#), [GiNaC::make_hash_seed\(\)](#), [none](#), [GiNaC::rotate_left\(\)](#), [GiNaC::basic::setflag\(\)](#), and [type](#).

6.171.4.7 `validate()`

```
void GiNaC::symmetry::validate (  
    unsigned n)
```

Verify that all indices of this node are in the range [0..n-1].

This function throws an exception if the verification fails. If the top node has a type != none and no children, add all indices in the range [0..n-1] as children.

6.184.1 Detailed Description

This class holds an index with a variance (co- or contravariant).

There is an associated metric tensor that can be used to raise/lower indices.

6.184.2 Constructor & Destructor Documentation

6.184.2.1 [varidx\(\)](#)

```
GiNaC::varidx::varidx (
    const ex & v,
    const ex & dim,
    bool covariant = false)
```

Construct index with given value, dimension and variance.

Parameters

<i>v</i>	Value of index (numeric or symbolic)
<i>dim</i>	Dimension of index space (numeric or symbolic)
<i>covariant</i>	Make covariant index (default is contravariant)

6.184.3 Member Function Documentation

6.184.3.1 is_dummy_pair_same_type()

```
bool GiNaC::varidx::is_dummy_pair_same_type (
    const basic & other) const [override], [virtual]
```

Check whether the index forms a dummy index pair with another index of the same type.

Reimplemented from [GiNaC::idx](#).

References [covariant](#).

6.184.3.2 archive()

```
void GiNaC::varidx::archive (
    archive_node & n) const [override], [virtual]
```

Save (serialize) the object into archive node.

Archive the object.

Losely speaking, this method turns an expression into a byte stream (which can be saved and restored later on, or sent via network, etc.)

Reimplemented from [GiNaC::idx](#).

References [covariant](#), and [n](#).

6.184.3.3 read_archive()

```
void GiNaC::varidx::read_archive (
    const archive_node & n,
    lst & syms) [override], [virtual]
```

Load (deserialize) the object from an archive node.

Construct object from [archive_node](#).

Note

This method is essentially a constructor. However, constructors can't be virtual. So, if unarchiving routines are implemented as constructors one would need to define such a constructor in every class, even if all it does is simply calling constructor of a superclass.

Reimplemented from [GiNaC::idx](#).

References [covariant](#), and [n](#).

6.184.3.4 `match_same_type()`

```
bool GiNaC::varidx::match_same_type (
    const basic & other) const [override], [protected], [virtual]
```

Returns true if the attributes of two objects are similar enough for a match.

This function must not match subexpressions (this is already done by [basic::match\(\)](#)). Only attributes not accessible by [op\(\)](#) should be compared. This is also the reason why this function doesn't take the wildcard replacement list from [match\(\)](#) as an argument: only subexpressions are subject to wildcard matches. Also, this function only needs to be implemented for container classes because [is_equal_same_type\(\)](#) is automatically used instead of [match_same_type\(\)](#) if [nops\(\)](#) == 0.

6.186.1 Detailed Description

This class acts as a wildcard for [subs\(\)](#), [match\(\)](#), [has\(\)](#) and [find\(\)](#).

```
bool GiNaC::wildcard::match (

```
unsigned GiNaC::wildcard::calchash () const [override], [protected], [virtual]
```

Compute the hash value of an object and if it makes sense to store it in the objects [status_flags](#), do so.

The method inherited from class basic computes a hash value based on the type and hash values of possible members. For this reason it is well suited for container classes but atomic classes should override this implementation because otherwise they would all end up with the same hashvalue.

7.4.2 Macro Definition Documentation

7.4.2.1 GINAC_DECLARE_UNARCHIVER

```
#define GINAC_DECLARE_UNARCHIVER(  
    classname)
```

Value:

```
class classname ## _unarchiver  
{  
    static int usecount;  
public:  
    static GiNaC::basic* create();  
    classname ## _unarchiver();  
    ~ classname ## _unarchiver();  
};  
static classname ## _unarchiver classname ## _unarchiver_instance
```

Helper macros to register a class with (un)archiving (a.k.a.

(de)serialization).

Usage: put

`GINAC_DECLARE_UNARCHIVER(myclass);`

into the header file (in the global or namespace scope), and

`GINAC_BIND_UNARCHIVER(myclass);`

into the source file.

Effect: the 'myclass' (being a class derived directly or indirectly from `GiNaC::basic`) can be archived and unarchived.

Note: you need to use `GINAC_{DECLARE,BIND}_UNARCHIVER` incantations in order to make your class (un)archivable *even if your class does not overload 'read_archive' method*. Sorry for inconvenience.

How it works:

The 'basic' class has a 'read_archive' virtual method which reads an expression from archive. Derived classes can overload that method. There's a small problem, though. On unarchiving all we have is a set of named byte streams. In C++ the class name (as written in the source code) has nothing to do with its actual type. Thus, we need establish a correspondence ourselves. To do so we maintain a 'class_name' => 'function_pointer' table (see the `unarchive_table_t` class above). Every function in this table is supposed to create a new object of the 'class_name' type. The 'archive_node' class uses that table to construct an object of correct type. Next it invokes `read_archive` virtual method of newly created object, which does the actual job.

Note: this approach is very simple-minded (it does not handle classes with same names from different namespaces, multiple inheritance, etc), but it happens to work surprisingly well.

7.4.2.2 GINAC_BIND_UNARCHIVER

```
#define GINAC_BIND_UNARCHIVER(  
    classname)
```

Value:

```
classname ## _unarchiver::classname ## _unarchiver() \
{ \
    static GiNaC::unarchive_table_t table; \
    if (usecount++ == 0) { \
        table.insert(std::string(#classname), \
            &(classname ## _unarchiver::create)); \
    } \
} \
GiNaC::basic* classname ## _unarchiver::create() \
{ \
    return new classname(); \
} \
classname ## _unarchiver::~~ classname ## _unarchiver() { } \
int classname ## _unarchiver::usecount = 0
```

7.28.1 Detailed Description

Polynomial factorization (implementation).

The interface function `factor()` at the end of this file is defined in the `GiNaC` namespace. All other utility functions and classes are defined in an additional anonymous namespace.

Factorization starts by doing a square free factorization and making the coefficients integer. Then, depending on the number of free variables it proceeds either in dedicated univariate or multivariate factorization code.

Univariate factorization does a modular factorization via Berlekamp's algorithm and distinct degree factorization. Hensel lifting is used at the end.

Multivariate factorization uses the univariate factorization (applying a evaluation homomorphism first) and Hensel lifting raises the answer to the multivariate domain. The Hensel lifting code is completely distinct from the code used by the univariate factorization.

Algorithms used can be found in [Wan] An Improved Multivariate Polynomial Factoring Algorithm, P.S.Wang, Mathematics of Computation, Vol. 32, No. 144 (1978) 1215–1231. 7.46.1 Detailed Description

Implementation of some special functions related to elliptic curves.

The functions are: complete elliptic integral of the first kind `EllipticK(k)` complete elliptic integral of the second kind `EllipticE(k)` iterated integral `iterated_integral(a,y)` or `iterated_integral(a,y,N_trunc)`

Some remarks:

- All formulae used can be looked up in the following publication: [WW] Numerical evaluation of iterated integrals related to elliptic Feynman integrals, M.Walden, S.Weinzierl, arXiv:2010.05271
- When these routines and methods are used for scientific work that leads to publication in a scientific journal, please refer to this program as : M.Walden, S.Weinzierl, "Numerical evaluation of iterated integrals related to elliptic Feynman integrals", arXiv:2010.05271
- As these routines build on the core part of `GiNaC`, it is also polite to acknowledge C. Bauer, A. Frink, R. Kreckel, "Introduction to the GiNaC Framework for Symbolic Computation within the C++ Programming Language", J. Symbolic Computations 33, 1 (2002), cs.sc/0004015

7.48.1 Detailed Description

Implementation of some special functions that have a representation as nested sums.

The functions are: classical polylogarithm $\text{Li}(n,x)$ multiple polylogarithm $\text{Li}(\{m_1,\dots,m_k\},\{x_1,\dots,x_k\})$ $G(\{a_1,\dots,a_k\},y)$ or $G(\{a_1,\dots,a_k\},\{s_1,\dots,s_k\},y)$ Nielsen's generalized polylogarithm $S(n,p,x)$ harmonic polylogarithm $H(m,x)$ or $H(\{m_1,\dots,m_k\},x)$ multiple zeta value $\text{zeta}(m)$ or $\text{zeta}(\{m_1,\dots,m_k\})$ alternating Euler sum $\text{zeta}(m,s)$ or $\text{zeta}(\{m_1,\dots,m_k\},\{s_1,\dots,s_k\})$

Some remarks:

- All formulae used can be looked up in the following publications: [Kol] Nielsen's Generalized Polylogarithms, K.S.Kolbig, SIAM J.Math.Anal. 17 (1986), pp. 1232-1258. [Cra] Fast Evaluation of Multiple Zeta Sums, R.E.Crandall, Math.Comp. 67 (1998), pp. 1163-1172. [ReV] Harmonic Polylogarithms, E.Remiddi, J.A. Vermaseren, Int.J.Mod.Phys. A15 (2000), pp. 725-754 [BBB] Special Values of Multiple Polylogarithms, J.Borwein, D.Bradley, D.Broadhurst, P.Lisonek, Trans.Amer.Math.Soc. 353/3 (2001), pp. 907-941 [VSW] Numerical evaluation of multiple polylogarithms, J.Vollinga, S.Weinzierl, hep-ph/0410259
- The order of parameters and arguments of Li and zeta is defined according to the nested sums representation. The parameters for H are understood as in [ReV]. They can be in expanded — only 0, 1 and -1 — or in compactified — a string with zeros in front of 1 or -1 is written as a single number — notation.
- All functions can be numerically evaluated with arguments in the whole complex plane. The parameters for Li, zeta and S must be positive integers. If you want to have an alternating Euler sum, you have to give the signs of the parameters as a second argument s to $\text{zeta}(m,s)$ containing 1 and -1.

- The calculation of classical polylogarithms is speeded up by using Bernoulli numbers and look-up tables. S uses look-up tables as well. The zeta function applies the algorithms in [Cra] and [BBB] for speed up. Multiple polylogarithms use Hoelder convolution [BBB].
- The functions have no means to do a series expansion into nested sums. To do this, you have to convert these functions into the appropriate objects from the nestedsums library, do the expansion and convert the result back.
- Numerical testing of this implementation has been performed by doing a comparison of results between this software and the commercial M..... 4.1. Multiple zeta values have been checked by means of evaluations into simple zeta values. Harmonic polylogarithms have been checked by comparison to $S(n,p,x)$ for corresponding parameter combinations and by continuity checks around $|x|=1$ along with comparisons to corresponding zeta functions. Multiple polylogarithms were checked against H and zeta and by means of shuffle and quasi-shuffle relations.

7.64.1 Detailed Description

This file contains the interface to the underlying bignum package.

Its most important design principle is to completely hide the inner working of that other package from the user of `GiNaC`. It must either provide implementation of arithmetic operators and numerical evaluation of special functions or implement the interface to the bignum package.
